Coverings of $\mathbb{P}^1 - \{0, 1, \infty\}$ with restricted "vertical" ramifications.¹⁾

Yasutaka Ihara
RIMS, Kyoto University

Let S be any set of prime numbers, and put

$$\mathbb{Z}_S = \mathbb{Z}[\frac{1}{p}; p \in S],$$

\mathbb{Q}_S : the maximal Galois extension over \mathbb{Q} unramified outside S^∞

So, $\pi_1(\text{Spec } \mathbb{Z}_S) = \text{Gal}(\mathbb{Q}_S/\mathbb{Q})$. We propose to study the action of this group on

$$\pi_1^{<S>} := \text{Ker}(\pi_1(\mathbb{P}^1 - \{0, 1, \infty\}/\mathbb{Z}_S) \rightarrow \pi_1(\text{Spec } \mathbb{Z}_S)),$$

where

$$\mathbb{P}^1 - \{0, 1, \infty\}/\mathbb{Z}_S = \text{Spec } \mathbb{Z}_S[t, 1/t, 1/(1-t)] \quad (t: \text{a variable}).$$

In terms of Galois theory of function fields, $\pi_1^{<S>} = \text{Gal}(\mathbb{M}_S/\mathbb{Q}_S(t))$,

where:

$$\begin{array}{c} M \quad \dots \quad \max \text{ Gal}/\mathbb{Q}(t) \text{ unram. outside } t=0,1,\infty \\ | \\ \pi_1^{<S>} \left\{ \begin{array}{l} M_S \text{ --- } \bar{\mathbb{Q}} \cdot M_S \\ | \text{ --- } \max \text{ Gal}/\mathbb{Q}(t) \text{ in } M \text{ in which } v_\ell(\ell \notin S) \\ \text{ --- } \bar{\mathbb{Q}}(t) \\ | \text{ --- } \text{are all unramified.} \\ \mathbb{Q}(t) \text{ --- } \mathbb{Q}_S(t) \text{ --- } \bar{\mathbb{Q}}(t) \end{array} \right. \end{array}$$

Here, v_ℓ is the unique extension of the ℓ -adic valuation of \mathbb{Q} to $\mathbb{Q}(t)$ such that ℓ is a prime element and the residue class of t is transcendental over \mathbb{F}_ℓ .

¹⁾ Although the titles are not the same, this is a resumé of my talk at the conference on March 28, 94.

We have the following two short exact sequences

$$(*) \quad 1 \rightarrow \text{Gal}(M/\overline{\mathbb{Q}}_{M_S}) \rightarrow \text{Gal}(M/\overline{\mathbb{Q}}(t)) \rightarrow \text{Gal}(M_S/\overline{\mathbb{Q}}_S(t)) \rightarrow 1,$$

$$\quad \quad \quad \parallel \quad \quad \quad \parallel$$

$$\quad \quad \quad \hat{F}_2 \text{ (free profinite)} \quad \pi_1^{<S>}$$

$$\quad \quad \quad \text{rank } 2$$

$$(**) \quad 1 \rightarrow \pi_1^{<S>} \rightarrow \text{Gal}(M_S/\overline{\mathbb{Q}}(t)) \rightarrow \text{Gal}(\overline{\mathbb{Q}}_S/\overline{\mathbb{Q}}) \rightarrow 1.$$

The most basic question is, perhaps, whether $(**)$ is useful in the (future) study of $\text{Gal}(\overline{\mathbb{Q}}_S/\overline{\mathbb{Q}})$. I cannot say anything about this now. Here, I state some results of my "first thought" related to $(*)$, $(**)$.

Terminology: "S-number": integers whose prime factors all belong to S ;

"S-group": finite group whose order is an S-number;

"pro-S group": proj. limit of S-groups ($|S|=1 \Rightarrow$ pro-nilpotent,

$|S|=2 \Rightarrow$ prosolvable).

$F_2^{\text{pro-S}}$: the pro-S completion of the free group of rank 2, i.e., the projective limit of all finite S-groups appearing as quotients of F_2 .

Statement of results:

(i) Ramification indices of $t=0,1,\infty$ in any finite subextensions of $M_S/\mathbb{Q}_S(t)$ are S -numbers.²⁾

(ii) For any open subgroup $H \subset \pi_1^{\langle S \rangle}$, its abelianization H^{ab} is a direct product of a pro- S group and a finite group.

These two are saying that $\pi_1^{\langle S \rangle}$, as a quotient of \hat{F}_2 , is not so big. The next (iii) says something to the opposite direction.

(iii) $\text{Gal}(M/\mathbb{Q} M_S)$, the kernel in (*), contains no non-trivial S -group as its quotient. In particular, $\hat{F}_2 \rightarrow F_2^{\text{pro-}S}$ factors through $\pi_1^{\langle S \rangle}$, as $\hat{F}_2 \rightarrow \pi_1^{\langle S \rangle} \rightarrow F_2^{\text{pro-}S}$ (both \rightarrow are surjective).

About the exact sequence (**),

(iv) The standard Puiseux embedding $M \hookrightarrow \bar{\mathbb{Q}}\{\{t\}\} = \bigcup_{N \geq 1} \bar{\mathbb{Q}}(t^{1/N})$ induces $M_S \hookrightarrow \mathbb{Q}_S\{\{t\}\}$, and M_S is stable under the coefficientwise $\text{Gal}(\mathbb{Q}_S/\mathbb{Q})$ -action on $\mathbb{Q}_S\{\{t\}\}$. This $\text{Gal}(\mathbb{Q}_S/\mathbb{Q})$ -action on $M_S/\mathbb{Q}(t)$ gives a "nice" splitting of (**).

Remarks If $S = \emptyset$, then $\mathbb{Q}_S = \mathbb{Q}$, $M_S = \mathbb{Q}(t)$ and $\pi_1^{\langle S \rangle} = \{1\}$.

When $S = \{p\}$, I do not know whether $\pi_1^{\langle p \rangle} \cong F_2^{\text{pro-}p}$ or not.

When $S = \{2, p\}$ ($p \neq 2$), $\pi_1^{\langle S \rangle}$ is not a pro- S group.

When $S = \{\text{all primes}\}$, then $\mathbb{Q}_S = \bar{\mathbb{Q}}$, $M_S = M$ and $\pi_1^{\langle S \rangle} = \hat{F}_2$.

²⁾ This property depends on the choice of three points on \mathbb{P}^1 ; $t=0,1,\infty$. If they were, e.g., $t=0,12^3,\infty$, then this property would not hold (unless $S \ni 2,3$)

Main ingredients for proofs.

(i) As T. Saito noted, (i) is obtained directly from the generalized Abhyankar lemma ([SGA1] Exp XIII).

(ii) This proof relies on a result of Coleman [Co].

More precisely, it is reduced to the following statement which is (essentially) in [Co]:

Let A be an abelian variety over a number field k , and S be any set of primes of k . Assume A has good reduction outside S . For each positive integer n with $(n, S) = 1$, let $A[n]$ denote the group of all n -torsion points of $A(\bar{k})$, and $K[n]$ be its subgroup generated by the kernel of reduction mod v in $A[n]$, where v runs over all prime divisors of the field $k(A[n])$ dividing n . Then the order of $A[n]/K[n]$ is bounded by a positive number which depends only on A and k (in fact, only on $A \otimes \bar{\mathbb{Q}}$).

(iii) The proof relies on standard arguments of Grothendieck's ([SGA1]) on descent of étale coverings; the only additional points to be checked are:

(a) For any finite subextension $L/\mathbb{Q}_S(t)$ in M_S , the integral closure of $\mathbb{P}^1/\mathbb{Z}_S$ in L is regular outside S (including points above $t=0, 1, \infty$ as long as they are not above S).

(b) The pro- S completion of the fundamental group of a compact Riemann surface of genus > 1 has trivial center.

The assertion (a) can be checked easily, while (b) is proved in [Na].

(iv) The point is to prove the \mathbb{Q}_S -rationality of places of M_S above $t \rightarrow 0, 1, \infty$. This follows by using the purity of branch loci on suitable Fermat curves whose exponents are S -numbers.

Some open problems:

(Problem I) Characterize $\pi_1^{\langle S \rangle}$ as quotient of \hat{F}_2 .

Related questions:

(Q1) Is $\pi_1^{\langle S \rangle}$ the biggest quotient of \hat{F}_2 on which $\text{Gal}(\bar{\mathbb{Q}}/\mathbb{Q}_S)$ acts trivially?

(Q2) Is the center of $\pi_1^{\langle S \rangle}$ trivial?

(Q3) In connection with the result (ii), let H_0^{ab} denote the coprime-to- S part of the torsion subgroup of H^{ab} . Then what can one say about the group $\varprojlim_H H_0^{ab}$?

(Problem II) Is the homomorphism

$$\varphi_S : \text{Gal}(\mathbb{Q}_S/\mathbb{Q}) \rightarrow \text{Aut } \pi_1^{\langle S \rangle}$$

(defined by the splitting (iv) of the exact sequence (**)) injective?

When $S = \{\text{all primes}\}$, φ_S is injective by the well-known injectivity of Belyi for the Galois representation $\text{Gal}(\bar{\mathbb{Q}}/\mathbb{Q}) \rightarrow \text{Out } \hat{\pi}_1(P^1 - \{0, 1, \infty\}/\mathbb{Q})$.

I do not know at present whether φ_S is injective in any other cases, e.g. even when $S = \{\text{all primes}\} - \{p\}$.

In general, let \mathbb{Q}_S^* ($\mathbb{Q} \subset \mathbb{Q}_S^* \subset \mathbb{Q}_S$) denote the field corresponding to the kernel of φ_S . What we know about \mathbb{Q}_S^* :

(*) \mathbb{Q}_S^* contains all higher circular S -units (the obvious generalization of higher circular l -units in [A-I]).

(**) Let $n \geq 1$, and $S = S_n = \{p; p \text{ divides } n(n-1)\}$. Assume $\pi_1^{\langle S \rangle}$ is center-free. Then \mathbb{Q}_S^* contains the splitting field of the equation

$$x^{n-2} + 2x^{n-3} + 3x^{n-4} + \dots + (n-1) = 0.$$
